Graph Theory Origins [5, 7]

Figure: Euler's Bridges Conceptualization (Recreation)

Early Applications of Graphs in Mathematics

- Graph theory attributed to begin with Euler and the "Seven Bridges of Königsberg" (\sim 1736)
- Random graph theory began developing in \sim 1940's (Moreno and Jennings) but most notably with the Erdös-Rényi random graph (1958)
- Ising model (\sim 1920's) proposed graphical model of interactions of atomic spin
- Statistical "beginnings"

graphical neural networks

- Arthur Dempster (founding Harvard Stats professor) introduced covariate selection by precision matrix estimation in 1972 [3]
- Judea Pearl ~1980's for causal interretation of Bayesian networks
- Modern interest in related regularized M-estimation problems and

Graphical Model Motivation

Suppose you have 20 random variables*, how do you model their interrelationship? *Consider any of the following:

- General -omic data
- Spatial data
- Computational neuroscience data
- Clinical language (see: EHR LLM^a)
- Time-series data

^aElectronic Healthcare Record Large Language Model

Graphs

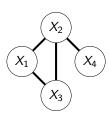

- Graphs are a natural way to represent interrelationships among our data!
- Present nice properties for estimation of joint distributions
 - Can avail existing graphical algorithms
 - Ability to characterize conditional (in)dependencies
- Probabilistic graphical modelling provide a general formalism of many existing methods in statistics (e.g. Bayesian hierarchical modelling, Hidden Markov Models, Kalman filter)
- Wainwright, Jordan "Graphical Models, Exponential Families, and Variational Inference" (2007) is an excellent reference for further applications (and theory) behind graphical models [8]³

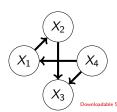

Graphs

- Consider random vector $X \sim \mathcal{N}(\boldsymbol{\mu}, \Sigma)$ and precision matrix $\Theta \equiv \Sigma^{-1}$
 - Interested in estimating Σ to characterize joint distribution f_X
- Can construct a resulting graph $\mathcal{G} = (V, E)$, $V = X, E \subseteq V \times V$
 - Let ne(x) represent the neighborhood of x, or $ne(x) = \{b \in V \mid (x, b) \in E\}$
- Can construct adjacency matrix $A \in \mathbb{R}^{|V| \times |V|}$ describing edge set E
 - $\bullet \ A_{ij} = \mathbb{I}\{(i,j) \in E\}$
- Gaussianity gives us the nice property that $\Theta_{ij} = 0 \Leftrightarrow X_i \perp X_j | X_{-\{i,j\}}$

Undirected Graph

Directed Graph

Notation/Nomenclature

Omitting some philosophical discrepancies

Directed (Acyclic) Graph
⇔ Bayesian network

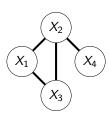

Undirected graph
⇔ Markov network / Markov random field

Graphs

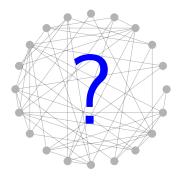

- Consider random vector $X \sim N(\mu, \Sigma)$ and precision matrix $\Theta \equiv \Sigma^{-1}$
 - Interested in estimating Σ to characterize joint distribution f_X
- Can construct a resulting graph $\mathcal{G} = (V, E)$, $V = X, E \subseteq V \times V$
 - Let ne(x) represent the neighborhood of x, or $ne(x) = \{b \in V \mid (x, b) \in E\}$
- ullet Can construct adjacency matrix $A \in \mathbb{R}^{|V| imes |V|}$ describing edge set E
 - $A_{ii} = \mathbb{I}\{(i,j) \in E\}$
- Gaussianity gives us the nice property that $\Theta_{ii} = 0 \Leftrightarrow X_i \perp X_i | X_{-\{i,j\}}$

Undirected Graph

How do we estimate graph structure?

Outline (Redux)

- Introduction to Graphical Models
- Estimation for Complete Data
 - Neighborhood Selection
 - Graphical Lasso
 - Further Notes
- Stimation with Missingness
 - General Methods
 - Erose Data and GI-JOE

Preface

interest EDIT do you do anything differently if so?

• $X = (X_1, ..., X_d)$ may or may not contain a "response variable" of

- \bullet Identifying conditional relationships \Leftrightarrow Estimating/Identifying 0's in Σ
- ullet Enforse sparsity for $\hat{\Theta}$ to account for S
- Exhaustive search is quickly infeasible, but can yield solutions with theoretical guarantees
 - Consistency
 - Nice statistical rates

Neighborhood Selection

- Note that E\{ne(X_i)} includes all nodes independent of X_i conditional upon ne(X_i)
- Proposed by Meinshausen & Bühlmann (2006) [6], for $X \in \mathbb{R}^d$ concern yourself only with $(\Theta)_{ij} = 0$, or $(\Theta)_{ij} \neq 0$
- Assume sparsity of Θ and fit d, element-wise lasso models
 - Regress $X_i \overset{\mathsf{Lasso}}{\sim} X_1 + ... X_{i-1} + X_{i+1} + ... + X_d$ for all $i \in [d]$
 - Take $\hat{\beta}_{(-i)} \in \mathbb{R}^{d-1}$ from each model
 - Conclude⁴ $(\Theta)_{ij} = 0 \Leftrightarrow \hat{\beta}_{(-i)j} = 0 \land \hat{\beta}_{(-j)i} = 0$
- \bullet Admits asymptotic consistency for "zero-selection" of Θ

Authors both AND or OR rule for final step with similar performance

18 / 40

Dominic DiSanto Graphical Models November 30, 2023

Neighborhood Selection

Potential Drawbacks:

- Fitting d regression models is almost assuredly redundant
- Although consistent, does not exactly compute but approximates the joint likelihood over X, and thus does not necessarily produce MLE [1]
- ullet $\hat{\Theta}$ is *not* guaranteed to be positive semi-definite
- Requires sparsity assumptions for theoretical guarantees:
 - $\exists \kappa$, $\max_{a \in V} |\operatorname{ne}(a)| = O(n^{\kappa})$
 - For any conected nodes a,b (i.e. $\forall (a,b) \in E$), $||\theta^{a,\text{ne}(b)\setminus\{a\}}||_1 \leq \vartheta < \infty$

Graphical Lasso

Natural extension, why not just maximize the log-likelihood?

$$\hat{\Theta}_{\textit{MLE}} = \textit{argmax}_{\Theta} \left\{ \log \det \Theta - \text{trace}(S\Theta) \right\}$$

For N < d, we have the empirical covariance matrix $S = n^{-1} \sum X_i X_i^T$ is rank-degenerate, and the MLE does not exist! Prove, 9.2c in SLS

Graphical Lasso

So we assume sparsity and apply the ℓ_1 penalty

$$\hat{\Theta}_{\lambda, \textit{MLE}} = \textit{argmax}_{\Theta} \left\{ \log \det \Theta - \text{trace}(S\Theta) - \lambda \sum_{i \neq j} |\Theta_{ij}| \right\}$$

What does this give us?

- True graph recovery for $N = \Omega(d^2 \log p)$
- Convex pogram, quickly optimizable

Simulations (Complete Data)

- glasso package in R can fit Graphical Lasso as well as neighborhood-selection approximation
- sklearn has similar sklearn.covariance.graphicallasso command
- skggm extends Gaussian Graphical Model methods
- Simulation/data set-up detailled here, banded/AR, block, and ER graph

Simulations (Complete Data)

Graphs here

Further Notes

- Neighborhood Selection maximizes d conditional likelihoods
- GLasso maximizes an ℓ_1 penalized, joint (Gaussian) likelihood
- (Highly non-trivial) extensions beyond Gaussianity exist:
 - REVIEW/ADD/EDIT be able to speak in some depth
 - Heterogenous graphs (specifically mixture of Gaussian, Exponential, Poisson, Binomial nodes) [2]
 - Non-parametric extensions [4]

Motivation

- Methods above largely assume complete data⁵
- Networks change, measurement availability (and quality) varies
- Measurement is also often differential between nodes

Visualization here

⁵In the Gaussian setting, hidden/unobserved nodes or missingness can be mean-imputed, but this is fairly näive/addahessides procedure

Naïve Methods with Missingness

Results with nhood, GLasso in grahpicswith missingness

Erose Data and GI-JOE

Graphs, how and why (revisited)?

Conclusion

- Graphs are a powerful representation of your multivariate data (intuitively and algorithmically)
- Useful, theoretical extensions may follow more immediately under the graphical model formalism
- These extensions tend⁶ to distill to regularized M-estimation problems, an area with great theoretical contributions and guarantees
- Extensions beyond Gaussianity substantially increase complexity

Appendix Slides

Forgoing Sparsity Assumptions

In the above methods, we have almost uniformly assumed some sparsity and applied a penalty (ℓ_1)

- How often is this a viable assumption?
- What do we do (or what happens) if we don't meet this sparsity requirement?

Time-Series Data

- Consider that our repeated observations are time-indexed:
 - $\{X_j(t), t \in \mathcal{T}, j = 1, ..., N\}, X_j \in \mathbb{R}^d$
- Graphical perspective of vector auto-regressive models
 - $X_d(t) = \varepsilon_d(t) + \sum_{j \neq d} \sum_{t \in \mathcal{T}} \alpha_t X_j(t)$
- Can infer "Granger causal" relationships
 - Causal relationships for some time-series using prior data from a different time series

See Michael Eichler's "Granger-causality graphs for multivariate time series" (2007) and Dahlhaus's and Eichler's (2003) "Causality and graphical models in time series" for further discussion

Downloadable Slides

Inference with Debiased Lasso

- The typical lasso estimator $\hat{\beta}_{\lambda} = \operatorname{argmin} \beta ||Y X\beta||_2^2 + \lambda ||\beta||_1$ is biased for true $beta^*$
- ullet Can construct debiased estimator \hat{eta}_{λ}^{d} with asymptotic normality
- What inference does this permit in graphical models that use ℓ_1 penalization?

"Nothing new under the sun"

My (likely useless and certaintly non-falsifiable) conspiracy theory: Did Euler *really* originate graph theory? For how intuitive graphs seem to understanding interrelationships, this much have existed in some primitive form? Or for how financially relevant this seems, I'm sure some BCE gambler had an idea of "interconnectedness"

For our historical blinders, see Babylonian and Chinese origins of the Pythagorean Theorem

Thoughts, possible leads? Let me know!
